

Burp Suite - Extensions

The Extensions Interface

1. **Extensions List:** The top box displays a list of the extensions that are currently installed in Burp Suite for the current project. It allows you to activate or deactivate individual extensions.
2. **Managing Extensions:** On the left side of the Extensions interface, there are options to manage extensions:
 - **Add:** You can use this button to install new extensions from files on your disk. These files can be custom-coded modules or modules obtained from external sources that are not available in the official BApp store.
 - **Remove:** This button allows you to uninstall selected extensions from Burp Suite.
 - **Up/Down:** These buttons control the order in which installed extensions are listed. The order determines the sequence in which extensions are invoked when processing traffic. Extensions are applied in descending order, starting from the top of the list and moving down. The order is essential, especially when dealing with extensions that modify requests, as some may conflict or interfere with others.
3. **Details, Output, and Errors:** Towards the bottom of the window, there are sections for the currently selected extension:

- **Details:** This section provides information about the selected extension, such as its name, version, and description.
- **Output:** Extensions can produce output during their execution, and this section displays any relevant output or results.
- **Errors:** If an extension encounters any errors during execution, they will be shown in this section. This can be useful for debugging and troubleshooting extension issues.

The BApp Store

allows us to easily discover and integrate official extensions seamlessly into the tool. Extensions can be written in various languages, with Java and Python being the most common choices.

The screenshot shows the Burp Suite BApp Store interface. At the top, there are tabs: 'Installed', 'BApp Store' (selected), 'APIs', 'BChecks', and 'Extensions settings'. A yellow circle with the number '1' is placed over the 'Extensions settings' tab. Below the tabs, there is a search bar with the text 'Request timer' and a yellow circle with the number '2' next to it. The main content area is divided into two sections. On the left, there is a table with columns: 'Name', 'Installed', 'Rating', 'Popularity', 'Last updated', 'System imp...', and 'Detail'. The table contains one row for 'Request Timer' with a rating of 5 stars and a popularity bar. A yellow circle with the number '3' is placed over the 'Request Timer' row. On the right, there is a detailed view of the 'Request Timer' extension. It includes a description, 'Estimated system impact' (Overall: Low), and an 'Install' button. A yellow circle with the number '4' is placed over the 'Install' button. At the bottom of the interface, there are buttons for 'Refresh list' and 'Manual install ...'.

1. Switch to the **BApp Store** sub-tab in Burp Suite.
2. Use the search function to find **Request Timer**. There should only be one result for this extension.
3. Click on the returned extension to view more details.
4. Click the **Install** button to install the Request Timer extension.

Jython

To use Python modules in Burp Suite, we need to include the Jython Interpreter JAR file, which is a Java implementation of Python. The Jython Interpreter enables us to run Python-based

extensions within Burp Suite.

To use Python modules in Burp Suite, we need to include the Jython Interpreter JAR file, which is a Java implementation of Python. The Jython Interpreter enables us to run Python-based extensions within Burp Suite.

Current Version

The current version of Jython is 2.7.3. It can be downloaded here:

- [Jython Installer](#): Use this to install Jython. ([metadata](#))
- [Jython Standalone](#): Use this to run Jython without installing or to embed Jython in a Java application. ([metadata](#))
- You may cite Jython 2.7.3 as a [dependency in your Maven or Gradle build](#).

For information on installing see [Installation](#).

This version is supported on Java 8 (minimum) and 11.

1. **Configure Jython in Burp Suite**: Open Burp Suite and switch to the **Extensions** module. Then, go to the **Extensions settings** sub-tab.
2. **Python Environment**: Scroll down to the "Python environment" section.
3. **Set Jython JAR Location**: In the "Location of Jython standalone JAR file" field, set the path to the downloaded Jython JAR file.

The Burp Suite API

API endpoints that allow you to create and integrate your modules with Burp Suite. These APIs expose various functionalities, enabling you to extend the capabilities of Burp Suite to suit your specific needs.

Burp Suite supports multiple languages for writing extensions, such as:

1. Java (Natively): You can directly use Java to write extensions for Burp Suite, taking advantage of the powerful APIs available.
2. Python (via Jython): If you prefer Python as your programming language, you can utilize Jython, which is a Java implementation of Python to create Burp Suite extensions.
3. Ruby (via JRuby): Developers familiar with Ruby can leverage JRuby, a Java implementation of Ruby, to build Burp Suite extensions.

PortSwigger provides a comprehensive reference that is an excellent resource for developing Burp Suite extensions. [documentation](#)
